Motivation I

Motivation

Motivation I

Motivation II

Static Model

Empirical Example I

Dynamic Model

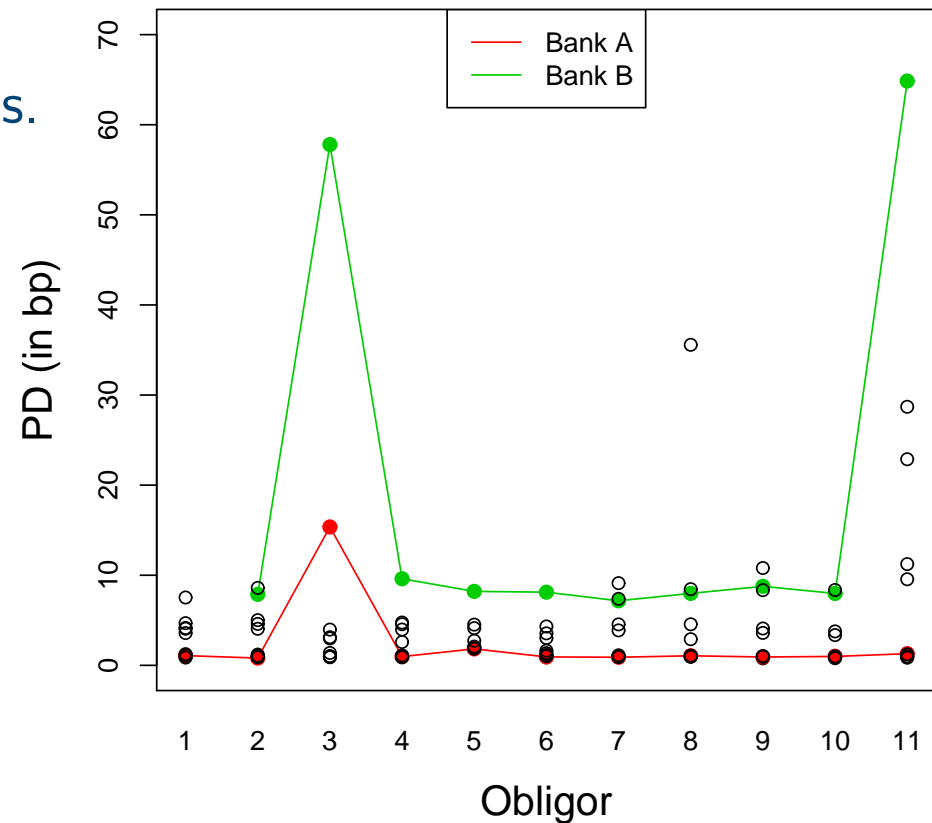

Estimation

Empirical Example II

Summary

Multi-rater panel provides information about rating heterogeneity

- ✓ across obligors,
- ✓ across raters,
- ✓ across time points.

Motivation II

Motivation

Motivation I

Motivation II

Static Model

Empirical Example I

Dynamic Model

Estimation

Empirical Example II

Summary

- ✓ Rating validation:
 - ✗ How accurate (or precise) are PD estimates?
 - ✗ Measures of rating bias and “error variance”.
- ✓ Consensus PD:
 - ✗ What is the consensus PD estimate when ratings differ across raters?
- ✓ Explaining rating heterogeneity:
 - ✗ Opaqueness of industries (Morgan 2002),
 - ✗ Regional differences (Hornik et al. 2009).

Approach

Motivation

Approach

General Model I

General Model II

General Model III

Specific Models I

Specific Models II

Estimation

Offerings

Empirical Example I

Dynamic Model

Estimation

Empirical Example II

Summary

- ✓ Need for a probabilistic model.
- ✓ Our Approach: PD treated as latent variable
 - ✗ Ratings are noisy observations of PD.
 - ✗ Provides a probabilistic model to directly estimate the rating error of a rater.
 - ✗ Explore patterns of heterogeneity.
 - ✗ Can obtain the “consensus rating” of the obligor.
- ✓ Requirement: Multi rater panel with rating information on the same metric scale.
 - ✗ In practice: “PD ratings” (PD estimates by different raters for all obligors).

Specific Models II

Estimation

Offerings

Empirical Example I

Dynamic Model

Estimation

Empirical Example II

Summary

- ✓ Merton (1974): Distance to default of firm i

$$DD_i = a_i + b_i V_i$$

where V_i is the log asset value of firm i .

- ✓ The probability of default is given as $PD_i = \Phi(-DD_i)$ where

$$\Phi : (-\infty, +\infty) \rightarrow [0, 1]$$

is the distribution function of the standard normal distribution.

- ✓ Probit of the PD is linearly related to the log asset value.

Motivation

Static Model

Approach

General Model I

General Model II

General Model III

Specific Models I

Specific Models II

Estimation

Offerings

Empirical Example I

Dynamic Model

Estimation

Empirical Example II

Summary

- ✓ The “estimate” PD_{ij} as derived by rater j for the true PD of firm i is

$$PD_{ij} = \Phi(-DD_i + \epsilon_{ij})$$

where ϵ_{ij} is the corresponding error (which depends on j in particular).

- ✓ Motivates a multi-rater model where the rater effects (“errors”) are additive on the probit (Φ^{-1}, DD_i) scale, i.e.,

$$\Phi^{-1}(PD_{ij}) = -DD_i + \epsilon_{ij} = \Phi^{-1}(PD_i) + \epsilon_{ij}$$

- ✓ Similar considerations apply for PD models based on, e.g., logistic regression.

Specific Models II

Estimation

Offerings

Empirical Example I

Dynamic Model

Estimation

Empirical Example II

Summary

- ✓ Let $S_{ij} = \Phi^{-1}(PD_{ij})$ denote the *score* of the observed PD and $S_i = \Phi^{-1}(PD_i)$ the latent true PD score.
- ✓ Write μ_{ij} and σ_{ij} for the mean and standard deviation of ϵ_{ij} , respectively.
- ✓ The latent variable model can be written as

$$S_{ij} = S_i + \mu_{ij} + \sigma_{ij}Z_{ij}$$

where the standardized rating errors $Z_{ij} = (\epsilon_{ij} - \mu_{ij})/\sigma_{ij}$ have mean zero and unit variance.

Specific Models II

Estimation

Offerings

Empirical Example I

Dynamic Model

Estimation

Empirical Example II

Summary

- ✓ Simple model:

$$S_{ij} = S_i + \mu_j + \sigma_j Z_{i,j}$$

- ✗ Rating errors are independent of obligors and their characteristics (e.g., creditworthiness).
- ✗ Parameters depend on raters only: $\mu_{ij} = \mu_j, \sigma_{ij} = \sigma_j$.

- ✓ Extended model:

$$S_{ij} = S_i + \mu_{g(i),j} + \sigma_{g(i),j} Z_{ij}$$

- ✗ Groups of obligors with homogeneous rating error characteristics.
- ✗ Parameters depend on rater and obligor groups:
 $\mu_{ij} = \mu_{g(i),j}, \sigma_{ij} = \sigma_{g(i),j}$.

Specific Models II

Motivation

Static Model

Approach

General Model I

General Model II

General Model III

Specific Models I

Specific Models II

Estimation

Offerings

Empirical Example I

Dynamic Model

Estimation

Empirical Example II

Summary

- ✓ Ensuring identifiability:

Average rating bias within each obligor group is zero.

$$\mathbb{E}(S_{ij}) = \mathbb{E}(S_i) + \mu_{g(i),j} \text{ with } \sum_j \mu_{g,j} = 0.$$

- ✓ Modelling marginal group effects:

$$\mathbb{E}(S_i) = \nu_{g(i)}$$

$$\text{var}(S_i) = \tau^2 \text{ or } \text{var}(S_i) = \tau_{g(i)}^2.$$

Empirical Example I

Dynamic Model

Estimation

Empirical Example II

Summary

- ✓ Mixed-effects model for the observed S_{ij} ,
 - ✗ latent true PD scores S_i enter as random effects.

- ✓ Given parametric models for the μ_{ij} and σ_{ij} and the distributions of true PD scores and standardized rating errors.

- ✓ Estimation using R:
 - ✗ Marginal maximum likelihood: nlme (ratermodel), or
 - ✗ Bayesian techniques: rjags and coda

Residual Analysis

Dynamic Model

Estimation

Empirical Example II

Summary

- ✓ Data from the Austrian Credit Register from September 2007.
- ✓ Multi-rater panel containing:
 - ✗ obligor specific information (country, industry, ...),
 - ✗ rating information (original rating, PD).
- ✓ Include 13 banks which report PDs and have sufficiently many co-ratings (every bank has at least 4 co-ratings with every other bank).
 - ✗ 5432 co-ratings of 13 banks for 2090 obligors.

Model Selection

Motivation

Dynamic Model

Estimation

Empirical Example II

Summary

✓ Variety of models analyzed using AIC and BIC.

✗ Industry affiliation as grouping variable.

✗ Constant variance τ^2 for PD score.

$$S_{ij} = S_i + \mu_{g(i),j} + \sigma_{g(i),j} Z_{ij}, \quad S_i \sim N(\nu_{g(i)}, \tau^2),$$

$$\mathbb{E}(S_{ij}) = \mathbb{E}(S_i) + \mu_{g(i),j}, \quad \sum_j \mu_{g,j} = 0,$$

where

$\mu_{g,j}$ rating bias to the mean PD score of bank j for obligors in industry g ,

$\sigma_{g,j}$ standard deviation of the rating error of bank j for obligors in industry g , and

ν_g mean PD score in industry g .

Parameter Estimates I

Industry specific means:

Industry	ν_g	$\Phi(\nu_g)$	$\Phi(\nu_g - \tau)$	$\Phi(\nu_g + \tau)$
Manufac	-2.542	55.1	17.7	151.1
Energy	-2.993	13.8	3.8	44.2
Constr	-2.448	71.8	23.8	190.9
Trading	-2.375	87.7	29.8	227.5
Finance	-3.256	5.6	1.5	19.2
RealEst	-2.474	66.8	22.6	174.7
Public	-3.330	4.3	1.1	15.1
Service	-2.517	59.2	19.8	157.0
Private	-2.296	108.4	40.0	267.4

The corresponding standard deviation τ is 0.357 and the PD intervals are measured in basis points (10^{-4}).

Dynamic Model

Motivation

Simple Model

Market Model

Offerings

Estimation

Empirical Example II

Summary

- ✓ Formulate a statistical framework for a dynamic rating process:
 - ✗ Explaining the rating heterogeneity not only cross-sectionally but also longitudinally.
 - ✗ Intertemporal change of consensus ratings.
 - ✗ Effects of macroeconomic shocks – *systematic risk* (McNeil and Wendin, 2007).
 - ✗ Correlations in rating migrations (Stefanescu et al., 2009)
 - ✗ Evaluation of raters.

- ✓ Requirement: Multi-rater panel data with rating information on the same PD-scale.

Simple Model

Motivation

Static Model

Empirical Example I

Dynamic Model

Motivation

Simple Model

Market Model

Offerings

Estimation

Empirical Example II

Summary

✓ Simple Model:

$$S_{ij}(t) = S_i(t) + \mu_j + \sigma_j Z_{ij}(t),$$

- ✗ Rating errors are independent of obligors and their characteristics (e.g., creditworthiness).
- ✗ Parameters depend on raters only: $\mu_{ij} = \mu_j, \sigma_{ij} = \sigma_j$.
- ✗ Latent score $S_i(t)$ is assumed to follow an AR(1) process:

$$S_i(t) = \alpha_i S_i(t-1) + \nu_i(1 - \alpha_i) + \xi_i(t),$$

where $S_i(0) = \nu_i + \xi_i(0)$, $\nu_i \sim N(\nu, \tau^2)$ and $\xi_i(t) \sim N(0, \phi^2)$.

- ✗ AR(1) process induces auto-correlation in the latent credit worthiness of obligor i .
- ✗ Latent scores $S_i(t)$ are uncorrelated across obligors.

Market Model

Motivation

Static Model

Empirical Example I

Dynamic Model

Motivation

Simple Model

Market Model

Offerings

Estimation

Empirical Example II

Summary

- ✓ Let $f(t)$ denote a market factor, latent score $S_i(t)$ can then be written as

$$S_i(t) = \alpha_i S_i(t-1) + \nu_i(1 - \alpha_i) + \beta_{1,i} f_1(t) + \beta_{2,i} f_2(t) + \xi_i(t),$$

- ✗ $S_i(0) = \nu_i + \xi_i(0) + \beta_{1,i} f_1(0)$.
- ✗ $\beta_{j,i} \sim N(\mu_\beta, \sigma_\beta^2)$, ($j = 1, 2$) denotes cross sectional correlation coefficient of scores $S_i(t)$.
- ✗ Assume $f_1(t)$ follows AR(1) process
 $f_1(t) := \gamma f_1(t-1) + \zeta(t)$, $f_1(0) = \zeta(0) / \sqrt{1 - \gamma^2}$, and
 $f_2(t) \sim N(0, 1) \quad \forall t$ to simulate market volatility shocks.

Market Model

Offerings

Estimation

Empirical Example II

Summary

- ✓ Assessment of rater effects (rater heterogeneity) in terms of their μ/σ^2 bias/variance characteristics.
- ✓ Estimated random effects $\hat{S}_i(t)$ can be interpreted as the consensus rating for obligor i over time.
- ✓ Market correlation structure.
 - ✗ Can the market explain the correlation structure between the obligors?

Bayesian Approach

Motivation

Static Model

Empirical Example I

Dynamic Model

Estimation

Bayesian Approach

rjags

Bayesian Inference
using R

model.bug

Output diagnostic

Empirical Example II

Summary

- ✓ Both, *prior* and *likelihood* are used to derive the *posterior*
- ✗ $p(\theta|y) \propto p(y|\theta)p(\theta)$.
- ✓ *Informative* and *non-informative* priors $p(\theta)$
 - ✗ Prior denotes beliefs about parameter before observing data.
 - ✗ Allows for expert opinions through the use of informative priors → informative prior.
 - ✗ All information resulting in a prior arose from data → noninformative prior.
- ✓ Gibbs sampling is used to derive posterior distribution.

Summary

- ✓ Rating agencies provide ratings only on a ordinal scale
- ✗ Unclear whether PD or EL is measured.
- ✗ Unclear which time horizon.
- ✓ Long history of default rates available.
- ✓ However, agency ratings are widely used as PD-equivalents by the industry (Erlenmaier, 2006; Tasche, 2008).
- ✓ This study: Mapping of ordinal ratings to PD provided by OENB.
- ✓ **Note:** All results of this study are conditional on used mapping procedure.
- ✗ Quality of rating system can not be separated from mapping (in particular bias).

Summary

Summary

- ✓ This methodology can be used to make fundamental statements about the heterogeneity of raters of a multi-rater panel.
- ✓ The “consensus rating” of obligors can be estimated.
- ✓ Using the consensus rating a residual analysis can be performed for single obligors as well as obligor groups of interest.
- ✓ The effect of a market factor on the consensus can be estimated.

Requirement: The number of co-ratings within a subgroup must be sufficiently large.
